Abstract
A case study is described in which four patients diagnosed at different stages of disease progression with the α-synuclein or Lewy body disorders Parkinson’s disease (PD) and Neurocognitive Disorder with Lewy Bodies (NCDLB) were treated with the acetylcholinesterase inhibitor (AChEI) Donepezil to address the symptoms of constipation, obstipation and impaction. In all four patients, the use of Donepezil was associated with significant symptom reduction, which was maintained at intervals of six, twelve, eighteen and thirty-six months, with no apparent reduction in bowel motility, nor the emergence of any new symptoms. The results suggest that the AChEI Donepezil can have long-term benefit in reducing the symptoms of constipation, obstipation and impaction in patients with α-synuclein disorders.

Keywords: Neurocognitive Disorder with Lewy Bodies, Parkinson’s disease, constipation, Donepezil, acetylcholinesterase inhibitor

Introduction
In an initial case study, the acetylcholinesterase inhibitor (AChEI) Donepezil was used to treat the symptoms of constipation, obstipation, and impaction in four patients diagnosed at different stages of disease progression with α-synuclein protein pathology, or Lewy body disorders including Parkinson’s disease (PD) and Neurocognitive Disorder with Lewy Bodies (NCDLB) [1]. Constipation in this context refers to reduced frequency of bowel movements to less than once in two days. Obstipation is defined as severe constipation, with frequency of bowel movements reduced to less than once a week. Impaction is defined as complete cessation of bowel function, also referred to as blockage of the lower intestine. The study was based on research demonstrating that α-synuclein impairment of the predominantly cholinergic neurotransmitter pathways in the myenteric plexus (MP) and the colonic submucosal plexus (CSMP) leads to bowel immotility, presenting symptomatically as constipation, obstipation and impaction [2-10].

To preserve basic motor functions including gait and balance, PD and NCDLB patients with significant Parkinsonian features are often prescribed L-dopa agents including Carbidopa-Levodopa (brand names include Sinemet and Stalevo) [11,12], whose potential side effects include bowel immotility [13]. A growing body of research finds that constipation, obstipation and impaction significantly diminish the patient’s quality of life, and create daily hardship for providers of care [14,15]. For patients with α-synuclein pathology, conventional forms of treatment including over-the-counter medications have proven largely ineffective for reducing symptoms of constipation, obstipation and impaction [16].

Donepezil and Constipation: Cholinergic Agonist Use in NCDLB and PD
PD and NCDLB patients have long been prescribed acetylcholinesterase inhibitors (AChEIs) to counter cholinergic impairment caused by α-synucleinopathy [17-22], including PD motor symptoms, gait dysfunction, levodopa-induced dyskinesias, cognitive deterioration, psychosis, sleep abnormalities, autonomic dysfunction, and altered olfactory function. The pathophysiology of these symptoms originates in alteration of the cholinergic tone in the striatum and/or to degeneration of cholinergic nuclei, most importantly the nucleus basalis magnocellularis and the pedunculopontine...
nucleus [21]. The AChE inhibitor Donepezil has demonstrated efficacy for mitigating cholinergic impairment in PD and NCDLB patients, without exacerbating Parkinsonian symptoms or generating new symptoms [23-28]. In a non-geriatric affective patient population, Donepezil was shown to be effective in reducing constipation [29], and in a population diagnosed with severe bowel immotility, Donepezil increased bowel contractions 477% [30].

Donepezil is a specific, reversible acetylcholinesterase inhibitor [31, 32]. By limiting the action of the acetylcholine-hydrolyzing enzyme acetylcholinesterase, Donepezil effectively increases acetylcholine levels, mitigating the symptoms of cholinergic impairment [33]. Also independently facilitating neuronal nicotinic acetylcholine receptors [34], Donepezil plays a dual role in reducing bowel immotility. This “dual action” has long made Donepezil a drug of choice for addressing symptoms of cholinergic impairment [22, 23, 25, 31, 34].

Hypothesis
Donepezil is well documented as an effective agent for reducing cholinergic impairment [23-28] and symptoms of constipation in non-geriatric affective patients [29], while increasing bowel contractions in patients with severe bowel immotility [30]. It was hypothesized that for patients diagnosed with PD and NCDLB, Donepezil would reduce the enteric nervous system (ENS) symptoms of constipation, obstipation and impaction consequent to α-synucleinopathy-based cholinergic impairment in the MP and CSMP. A secondary hypothesis was that Donepezil would reduce bowel immotility in patients using Carbidopa-Levodopa, often prescribed to Lewy body patients with Parkinsonian features.

Methods
A case study was conducted to assess Donepezil’s efficacy for mitigating α-synucleinopathy-based bowel immotility. Four patients diagnosed with PD and NCDLB at varying levels of disease progression with symptoms of constipation, obstipation and/or impaction were orally administered Donepezil in daily doses varying from 5 to 10 mg. Based on a series of MRI’s, neurological assessments, CT scans and Modified Hoehn and Yahr scores [35], two of the patients (Patient A and Patient B) had been diagnosed with PD. Patient A was a male aged 51 years at the time of diagnosis and 53 years at the time Donepezil was initially administered. Patient B was a male aged 70 years at the time of diagnosis and at the time that Donepezil was initially administered. Based on a series of MRI’s, CT scans, neurological evaluations, and scores on the Mini-Mental State Examination (MMSE) [36], the Quick Dementia Rating System (QDRS) [37] and the Lewy Body Composite Risk Score [38], the other two patients had been diagnosed with NCDLB (Patient C and Patient D). Patient C was a female aged 69 years at the time of diagnosis and at the time that donepezil was administered, and Patient D was a male aged 74 years at the time of diagnosis, and 78 years at the time that donepezil was initially administered. During the subsequent six months, one of the PD patients (Patient B) was also diagnosed with NCDLB, subsuming the PD symptoms leading to the initial PD diagnosis. Each patient was assessed before treatment, and after initiation of treatment at intervals of two, four, and six weeks, and six, twelve, eighteen and thirty-six months.

Results
After the introduction of orally administered Donepezil at daily doses of 5 mg, assessment at two weeks showed significant reduction of the symptoms of constipation, obstipation and impaction. In the current context, constipation is defined as BMs 3 times a week; obstipation by BMs 1-2 times a week; and impaction by BMs on a less than weekly basis, e.g., once in 2 weeks. Symptom reduction improved at assessment intervals of four weeks and six weeks. There was no increase in existing symptoms, nor the emergence of new symptoms at any assessment interval [1]. The increase in the frequency of bowel movements (BM’s) is shown in [Table 1].

Each of the four patients was assessed in a follow-up study six months later. Patient B showed cognitive decline and was assigned the diagnosis of NCDLB. Patient B and Patient D, both diagnosed with NCDLB, showed indication of disease progression in α-synucleinopathy-based cognitive and movement pathology, but no increase in the symptoms of constipation, obstipation or impaction, nor was there emergence of any new symptoms [39]. At the six month assessment, the daily dosage of Donepezil increased from 5 to 10 mg for Patient B, who showed increases in cognitive interference (short-term memory loss and difficulty with word-finding) leading to the change in diagnosis from PD to NCDLB.

Twelve months after the introduction of Donepezil, a second follow-up study was conducted using the same assessment procedure with each of the four patients. Each of the four patients showed no increase in symptoms of constipation, obstipation or impaction, nor apparent progression of any other α-synuclein symptoms, and no emergence of new symptoms [40]. The NCDLB patient (Patient B) whose dosage of Donepezil had been doubled at six months demonstrated recovery of cognitive function (reductions in short-term memory loss and difficulty with word-finding). Assessment at eighteen months using the same methodology showed no changes in symptoms status for any of the four patients [41].

At about twenty-four months, Patient B (diagnosed with NCDLB) was prescribed a daily oral dose of 10 mg of Vortioxetine. For treatment of Parkinsonian features, the patient was using Levodopa-Carbidopa (Sinemet), for which Donepezil had appeared effective in countering bowel slowing, and Bupropion for depression and anxiety. Vortioxetine was administered because it has demonstrated efficacy for reducing the symptoms of depression [42-55], anxiety [42, 56-57], and cognitive impairment [58-63]. Within two weeks of initiating the use of Vortioxetine, the patient received emergency treatment for impaction after 10 days without a bowel movement. The patient also demonstrated increased cognitive impairment. The use of Vortioxetine was discontinued, and within two days his cognition and bowel function returned to their pre-Vortioxetine status [64].

Thirty-six months after the initial introduction of Donepezil, the four patients were again assessed via the same procedure used at the previous intervals. In each patient, assessment indicated
no increase in constipation, obstipation, or impaction. Patients A and C showed no progression of cognitive interference, movement disorders or other α-synucleinopathy. Patients B and D both demonstrated progression of PD movement symptoms. None of the four patients showed indication of the emergence of new symptoms.

A summary of findings is presented in [Table 1].

**Discussion and Conclusions**

Daily oral administration of Donepezil in doses varying from 5 to 10 mg in four patients at varying levels of disease progression with PD and NCDLB was associated with significant reduction in the symptoms of constipation, obstipation and/or impaction. None of the four patients demonstrated the emergence of new symptoms, nor symptom progression for cognitive interference, movement disorders or other α-synucleinopathy. Mitigation of constipation, obstipation and/or impaction was consistent over time, assessed at intervals of two, four and six weeks, and later, at intervals of six, twelve, eighteen [1, 39-41] and thirty-six months.

The case study findings support the hypothesis that Donepezil can reduce α-synucleinopathy-based cholinergic impairment in the ENS, specifically the MP and CSMP, demonstrated by reductions in the symptoms of constipation, obstipation and/or

impaction. The case study findings also support the hypothesis that Donepezil can counter bowel immotility consequent to the use of Carbidopa-Levodopa.

The case study findings also provide a demonstration of Vortioxetine’s potential for serotoninergic and cholinergic inhibition, and importantly, its reversibility [63]. Vortioxetine is metabolized by cytochrome P450 enzymes (e.g., CYP450 2D6) and subsequently by uridine diphosphate glucuronosyltransferase [65]. Initially believed to have relatively low risk for pharmacodynamic drug interactions [66, 67], Vortioxetine peak plasma concentration and systemic exposure are significantly increased when Vortioxetine is co-administered with the potent CYP450 2D6 inhibitor Bupropion [65]. When co-administered, Levodopa-Carbidopa (Sinemet) also significantly increases Vortioxetine peak plasma concentration and systemic exposure [68, 69]. The NCDB patient in the case study prescribed Vortioxetine was using Bupropion and Levodopa-Carbidopa (Sinemet).

Apparently utilizing the same 5-HT3 receptor binding site as serotonin selective reuptake inhibitors (SSRIs), the molecular mechanisms underlying Vortioxetine’s site binding appear to vary from currently known 5-HT3A orthosteric ligands. In addition to binding in a similar manner to the serotonin class of competitive antagonists and 5-HT by interacting with residues of the aromatic box motif in the orthosteric binding site, Vortioxetine also interacts with residues not previously described to be important for the binding of either setrons or 5-HT, including Thr176 on loop B and Val202 on loop F [70]. Following partial agonist activity, Vortioxetine mounts what has been described as a persistent and insurmountable inhibition [70]. Vortioxetine’s peak plasma concentration and systemic exposure can be more than doubled by its combined interactions with Bupropion and Levodopa-Carbidopa [65, 68, 69], so its serotoninergic inhibitory potential is also significantly increased.

As illustrated by the case study, the combined interaction of Bupropion and Levodopa-Carbidopa with Vortioxetine can be dramatic, in this instance apparently exacerbating Lewy Body α-synuclein cholinergic suppression in the ENS, while the combination of Vortioxetine’s serotoninergic and cholinergic inhibition also significantly interfered with cognition. Although painful for the patient, this serendipitous finding contributed to the growing body of information about potential drug interactions for the relatively new drug Vortioxetine [64].

The primary focus of the case studies, however, continues to be Donepezil. Its “dual action” specifically and reversibly limits the action of the acetylcholine-hydrolyzing enzyme acetylcholinesterase [31, 32], while independently facilitating neuronal nicotinic acetylcholine receptors [34]. In combination, these two mechanisms effectively increase acetylcholine levels, with significant mitigation of symptoms attributable to cholinergic impairment [33].

The consistency of the current case study’s findings over a three year period in four patients diagnosed with degenerative α-synuclein neurocognitive and movement disorders is encouraging. It corroborates previous research indicating that Donepezil slows or reverses cognitive symptom progression in α-synucleinopathy, including short-term memory loss, difficulty with word-finding, hallucinations and cognitive interference [17, 18, 19, 20, 21]. It also provides a viable treatment protocol for mitigating α-synucleinopathy-based ENS suppression of the cholinergic pathways in the MP and the CSMP, providing relief from the symptoms of constipation, obstipation, and impaction that can so dramatically reduce the Lewy Body patient’s quality of life. Further research is recommended following patients over an extended time frame to establish longitudinal outcomes, and using larger numbers of subjects matched for diagnosis, age, gender and other variables.

Declarations:

Ethics approval and consent to participate: The Santa Barbara Cottage Hospital Institutional Review Board granted a waiver (#18-81ix) for this case study.

Conflict of Interest: The author declares that they have no conflict of interest.

Availability of data and materials: Data sharing is not applicable to this article as no datasets were generated or analyzed during the current study.

Funding: This research received no specific grant from any funding agency in the public, commercial or not-for-profit sectors.

Authors’ contributions: This paper was written according to the Ethical Principles of the American Psychological Association. Charles M. Lepkowsky, Ph.D. is the sole author of this work, including its conception and design; the acquisition, analysis, and interpretation of data; drafting, writing, and editing; final approval of the version published; and accepts accountability for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.
